Costs, called Local Costs, measured along said X- axis, said Local Cost Values being the smallest for the highest Accumulated Values;

performing a search for the left and right pedicle landmark location Candidates among the points of said X-axis associated to the smallest Local Costs.

7. The image processing method of claim 5, wherein the determination of the Region of Scanning comprises:

selecting an image of a current vertebra delimited by lines joining its corner landmarks;

estimating the median axis of the vertebra sides and the angle between said axis and a reference horizontal axis of the 2-D spine frontal image;

rotating the image of said current vertebra by said angle and defining an horizontal axis, which is the X-axis corresponding to said current vertebra; and limiting the rotated image by the leftmost and the rightmost projections of the vertebra corner landmarks on said X-axis, thus defining a rectangular image region used as Region of Scanning.

- 8. The image processing method of claim 5, wherein the Feature Values are the ridgeness values estimated in the Region of Scanning.
- 9. A system comprising a suitably programmed computer or a special purpose processor having circuit means, which are arranged
